EXERCISE

Overview

indexOf() method in String has some overloaded versions to configure the index where to start. This is used to count words in a string. Method is:

indexOf(int startIndex)

substring(int startIndex, int endIndex) method extracts the string in the given range.

Objectives

- Using overloaded versions of indexOf() method.

- Using substring() method to extract words.

Activities

```
public static String deleteAll(String
sentence, String word)
```

Write a static method with above signature.

This method gets a source string and removes all *searchWord* occurences inside source and returns the new string as case sensitive.

Example:
"Javathlon is the best resource to learn Java."
If the searchWord is Java, the result will be:
"thlon is the best resource to learn."
